# Where Are We?

# Where Are We?

# Biological Neurons (1/2)

- ▶ Brain architecture has inspired artificial neural networks.
- ▶ A biological neuron is composed of
  - Cell body, many dendrites (branching extensions), one axon (long extension), synapses
- ▶ Biological neurons receive signals from other neurons via these synapses.
- ▶ When a neuron receives a sufficient number of signals within a few milliseconds, it fires its own signals.

## Biological Neurons (2/2)

- ▶ Biological neurons are organized in a vast **network of billions of neurons**.
- ▶ Each neuron typically is **connected** to **thousands of other neurons**.

# A Simple Artificial Neural Network

- ▶ One or more binary inputs and one binary output
- ▶ Activates its output when more than a certain number of its inputs are active.

[A. Geron, O'Reilly Media, 2017]

# The Linear Threshold Unit (LTU)

- ▶ Inputs of a LTU are **numbers** (not binary).
- ▶ Each **input connection** is associated with a **weight**.
- ▶ Computes a **weighted sum of its inputs** and applies a **step function** to that **sum**.

- ▶  $z = w_1x_1 + w_2x_2 + \dots + w_nx_n = \mathbf{w}^T\mathbf{x}$

- ▶  $\hat{y} = \text{step}(z) = \text{step}(\mathbf{w}^T\mathbf{x})$

# The Perceptron

- ▶ The **perceptron** is a **single layer** of LTUs.
- ▶ The **input neurons** output whatever **input they are fed**.
- ▶ A **bias neuron**, which just **outputs 1 all the time**.
- ▶ If we use **logistic function (sigmoid)** instead of a **step** function, it computes a **continuous** output.

# How is a Perceptron Trained? (1/2)

- ▶ The **Perceptron training algorithm** is inspired by **Hebb's rule**.
- ▶ When a **biological neuron** often **triggers another neuron**, the **connection** between these two neurons grows **stronger**.

## How is a Perceptron Trained? (2/2)

- ▶ Feed one training instance  $\mathbf{x}$  to each neuron  $j$  at a time and make its prediction  $\hat{y}_j$ .
- ▶ Update the connection weights.

$$\hat{y}_j = \sigma(\mathbf{w}_j^T \mathbf{x} + b)$$

$$J(\mathbf{w}_j) = \text{cross\_entropy}(y_j, \hat{y}_j)$$

$$\mathbf{w}_{i,j}^{(\text{next})} = \mathbf{w}_{i,j} - \eta \frac{\partial J(\mathbf{w}_j)}{\partial w_i}$$

- ▶  $w_{i,j}$ : the weight between neurons  $i$  and  $j$ .
- ▶  $x_i$ : the  $i$ th input value.
- ▶  $\hat{y}_j$ : the  $j$ th predicted output value.
- ▶  $y_j$ : the  $j$ th true output value.
- ▶  $\eta$ : the learning rate.

# Perceptron in TensorFlow

# Perceptron in TensorFlow

```
n_neurons = 3
n_features = 2
```

```
model = keras.models.Sequential()
model.add(keras.layers.Dense(n_neurons, input_shape=(n_features,), activation="softmax"))
```

```
model.compile(loss="sparse_categorical_crossentropy", optimizer="sgd", metrics=["accuracy"])
model.fit(X_train, y_train, epochs=30)
```

# Multi-Layer Perceptron (MLP)

# Perceptron Weakness (1/2)

- ▶ Incapable of solving some trivial problems, e.g., XOR classification problem. Why?

A	B	A XOR B
0	0	0
0	1	1
1	0	1
1	1	0

$$\mathbf{X} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \\ 1 & 1 \end{bmatrix}$$

$$\mathbf{y} = \begin{bmatrix} 0 \\ 1 \\ 1 \\ 0 \end{bmatrix}$$

## Perceptron Weakness (2/2)

$$\mathbf{x} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \\ 1 & 1 \end{bmatrix}$$

$$\mathbf{y} = \begin{bmatrix} 0 \\ 1 \\ 1 \\ 0 \end{bmatrix}$$

$$\hat{y} = \text{step}(z), z = w_1 x_1 + w_2 x_2 + b$$

$$J(\mathbf{w}) = \frac{1}{4} \sum_{x \in \mathbf{X}} (\hat{y}(x) - y(x))^2$$

- ▶ If we minimize  $J(\mathbf{w})$ , we obtain  $w_1 = 0$ ,  $w_2 = 0$ , and  $b = \frac{1}{2}$ .
- ▶ But, the model outputs **0.5 everywhere**.

## Multi-Layer Perceptron (MLP)

- ▶ The **limitations** of Perceptrons can be eliminated by **stacking multiple Perceptrons**.
- ▶ The resulting network is called a **Multi-Layer Perceptron (MLP)** or **deep feedforward neural network**.

# Feedforward Neural Network Architecture

- ▶ A **feedforward neural network** is composed of:
  - One **input layer**
  - One or more **hidden layers**
  - One final **output layer**
  
- ▶ Every layer except the output layer includes a **bias neuron** and is **fully connected** to the **next layer**.

# How Does it Work?

- ▶ The **model** is associated with a **directed acyclic graph** describing how the functions are **composed together**.
- ▶ E.g., assume a network with just a **single neuron** in **each layer**.
- ▶ Also assume we have **three functions**  $f^{(1)}$ ,  $f^{(2)}$ , and  $f^{(3)}$  connected in a chain:  $\hat{y} = f(\mathbf{x}) = f^{(3)}(f^{(2)}(f^{(1)}(\mathbf{x})))$
- ▶  $f^{(1)}$  is called the **first layer** of the network.
- ▶  $f^{(2)}$  is called the **second layer**, and so on.
- ▶ The **length of the chain** gives the **depth of the model**.

# XOR with Feedforward Neural Network (1/3)

$$\mathbf{X} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \\ 1 & 1 \end{bmatrix}$$

$$\mathbf{y} = \begin{bmatrix} 0 \\ 1 \\ 1 \\ 0 \end{bmatrix}$$

$$\mathbf{W}_x = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$$

$$\mathbf{b}_x = \begin{bmatrix} -1.5 \\ -0.5 \end{bmatrix}$$

# XOR with Feedforward Neural Network (2/3)

$$\text{out}_h = \mathbf{XW}_x^T + \mathbf{b}_x = \begin{bmatrix} -1.5 & -0.5 \\ -0.5 & 0.5 \\ -0.5 & 0.5 \\ 0.5 & 1.5 \end{bmatrix} \quad \mathbf{h} = \text{step}(\text{out}_h) = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 0 & 1 \\ 1 & 1 \end{bmatrix}$$

$$\mathbf{w}_h = \begin{bmatrix} -1 \\ 1 \end{bmatrix} \quad \mathbf{b}_h = -0.5$$

# XOR with Feedforward Neural Network (3/3)

$$\mathbf{out} = \mathbf{w}_h^T \mathbf{h} + \mathbf{b}_h = \begin{bmatrix} -0.5 \\ 0.5 \\ 0.5 \\ -0.5 \end{bmatrix} \quad \text{step}(\mathbf{out}) = \begin{bmatrix} 0 \\ 1 \\ 1 \\ 0 \end{bmatrix}$$

# How to Learn Model Parameters $\mathbf{W}$ ?

## Feedforward Neural Network - Cost Function

- ▶ We use the **cross-entropy** (minimizing the negative log-likelihood) between the training data  $\mathbf{y}$  and the model's predictions  $\hat{\mathbf{y}}$  as the **cost function**.

$$\text{cost}(\mathbf{y}, \hat{\mathbf{y}}) = - \sum_j y_j \log(\hat{y}_j)$$

# Gradient-Based Learning (1/2)

- ▶ The **most significant difference** between the **linear models** we have seen so far and **feedforward neural network**?
- ▶ The **non-linearity** of a neural network causes its **cost functions** to become **non-convex**.
- ▶ Linear models, with **convex cost function**, **guarantee** to find **global minimum**.
  - Convex optimization converges starting from **any initial parameters**.

## Gradient-Based Learning (2/2)

- ▶ Stochastic gradient descent applied to **non-convex cost functions** has no such convergence guarantee.
- ▶ It is **sensitive** to the values of the **initial parameters**.
- ▶ For **feedforward neural networks**, it is important to **initialize** all **weights** to small random values.
- ▶ The **biases** may be **initialized** to **zero** or to **small positive values**.

# Training Feedforward Neural Networks

- ▶ How to **train** a **feedforward neural network**?
- ▶ For each training instance  $\mathbf{x}^{(i)}$  the algorithm does the following **steps**:
  1. **Forward pass**: make a **prediction** (compute  $\hat{\mathbf{y}}^{(i)} = \mathbf{f}(\mathbf{x}^{(i)})$ ).
  2. Measure the **error** (compute  $\text{cost}(\hat{\mathbf{y}}^{(i)}, \mathbf{y}^{(i)})$ ).
  3. **Backward pass**: go through each layer in **reverse** to measure the **error contribution** from **each connection**.
  4. **Tweak the connection weights** to **reduce the error** (update  $\mathbf{W}$  and  $\mathbf{b}$ ).
- ▶ It's called the **backpropagation** training algorithm

# Output Unit (1/3)

- ▶ **Linear units** in neurons of the **output layer**.
- ▶ **Output function**:  $\hat{y}_j = \mathbf{w}_j^T \mathbf{h} + b_j$ .
- ▶ **Cost function**: minimizing the **mean squared error**.

# Output Unit (2/3)

- ▶ **Sigmoid units** in neurons of the **output layer** (**binomial** classification).
- ▶ **Output** function:  $\hat{y}_j = \sigma(\mathbf{w}_j^T \mathbf{h} + b_j)$ .
- ▶ **Cost** function: minimizing the **cross-entropy**.

# Output Unit (3/3)

- ▶ **Softmax units** in neurons of the **output layer** (**multinomial** classification).
- ▶ **Output function**:  $\hat{y}_j = \text{softmax}(\mathbf{w}_j^T \mathbf{h} + \mathbf{b}_j)$ .
- ▶ **Cost function**: minimizing the **cross-entropy**.

# Hidden Units

- ▶ In order for the **backpropagation** algorithm to work properly, we need to **replace the step function** with **other activation functions**. **Why?**
- ▶ Alternative activation functions:
  1. **Logistic function (sigmoid)**:  $\sigma(z) = \frac{1}{1+e^{-z}}$
  2. **Hyperbolic tangent function**:  $\tanh(z) = 2\sigma(2z) - 1$
  3. **Rectified linear units (ReLU)**:  $\text{ReLU}(z) = \max(0, z)$

# Feedforward Network in TensorFlow

# Feedforward Network in TensorFlow

```
n_output = 3
n_hidden = 4
n_features = 2
```

```
model = keras.models.Sequential()
model.add(keras.layers.Dense(n_hidden, input_shape=(n_features,), activation="relu"))
model.add(keras.layers.Dense(n_output, activation="softmax"))
```

```
model.compile(loss="sparse_categorical_crossentropy", optimizer="sgd", metrics=["accuracy"])
model.fit(X_train, y_train, epochs=30)
```

# Dive into Backpropagation Algorithm

## Chain Rule of Calculus (1/2)

- ▶ Assume  $x \in \mathbb{R}$ , and two functions  $f$  and  $g$ , and also assume  $y = g(x)$  and  $z = f(y) = f(g(x))$ .
- ▶ The **chain rule of calculus** is used to compute the **derivatives of functions**, e.g.,  $z$ , formed by **composing other functions**, e.g.,  $g$ .
- ▶ Then the **chain rule** states that  $\frac{dz}{dx} = \frac{dz}{dy} \frac{dy}{dx}$
- ▶ Example:

$$z = f(y) = 5y^4 \text{ and } y = g(x) = x^3 + 7$$

$$\frac{dz}{dx} = \frac{dz}{dy} \frac{dy}{dx}$$

$$\frac{dz}{dy} = 20y^3 \text{ and } \frac{dy}{dx} = 3x^2$$

$$\frac{dz}{dx} = 20y^3 \times 3x^2 = 20(x^3 + 7) \times 3x^2$$

## Chain Rule of Calculus (2/2)

- ▶ Two paths chain rule.

$$z = f(y_1, y_2) \text{ where } y_1 = g(x) \text{ and } y_2 = h(x)$$

$$\frac{\partial z}{\partial x} = \frac{\partial z}{\partial y_1} \frac{\partial y_1}{\partial x} + \frac{\partial z}{\partial y_2} \frac{\partial y_2}{\partial x}$$

# Backpropagation

- ▶ Backpropagation training algorithm for MLPs
- ▶ The algorithm repeats the following steps:
  1. Forward pass
  2. Backward pass

# Backpropagation - Forward Pass

- ▶ Calculates outputs given input patterns.
- ▶ For each training instance
  - Feeds it to the network and computes the output of every neuron in each consecutive layer.
  - Measures the network's output error (i.e., the difference between the true and the predicted output of the network)
  - Computes how much each neuron in the last hidden layer contributed to each output neuron's error.

# Backpropagation - Backward Pass

- ▶ Updates weights by calculating gradients.
- ▶ Measures how much of these error contributions came from each neuron in the previous hidden layer
  - Proceeds until the algorithm reaches the input layer.
- ▶ The last step is the gradient descent step on all the connection weights in the network, using the error gradients measured earlier.

# Backpropagation Example

- ▶ Two **inputs**, two **hidden**, and two **output** neurons.
- ▶ Bias in **hidden** and **output** neurons.
- ▶ Logistic activation in all the neurons.
- ▶ Squared error function as the cost function.

# Backpropagation - Forward Pass (1/3)

- ▶ Compute the **output** of the **hidden layer**

$$\text{net}_{h1} = w_1x_1 + w_2x_2 + b_1 = 0.15 \times 0.05 + 0.2 \times 0.1 + 0.35 = 0.3775$$

$$\text{out}_{h1} = \frac{1}{1 + e^{\text{net}_{h1}}} = \frac{1}{1 + e^{0.3775}} = 0.59327$$

$$\text{out}_{h2} = 0.59688$$

## Backpropagation - Forward Pass (2/3)

- Compute the **output** of the **output layer**

$$\text{net}_{o1} = w_5 \text{out}_{h1} + w_6 \text{out}_{h2} + b_2 = 0.4 \times 0.59327 + 0.45 \times 0.59688 + 0.6 = 1.1059$$

$$\text{out}_{o1} = \frac{1}{1 + e^{\text{net}_{o1}}} = \frac{1}{1 + e^{1.1059}} = 0.75136$$

$$\text{out}_{o2} = 0.77292$$

## Backpropagation - Forward Pass (3/3)

- Calculate the **error** for each output

$$E_{o1} = \frac{1}{2}(\text{target}_{o1} - \text{output}_{o1})^2 = \frac{1}{2}(0.01 - 0.75136)^2 = 0.27481$$

$$E_{o2} = 0.02356$$

$$E_{\text{total}} = \sum \frac{1}{2}(\text{target} - \text{output})^2 = E_{o1} + E_{o2} = 0.27481 + 0.02356 = 0.29837$$

[<http://marimancusi.blogspot.com/2015/09/are-you-book-dragon.html>]

# Backpropagation - Backward Pass - Output Layer (1/6)

- ▶ Consider  $w_5$
- ▶ We want to know how much a **change** in  $w_5$  affects the **total error** ( $\frac{\partial E_{total}}{\partial w_5}$ )
- ▶ Applying the **chain rule**

$$\frac{\partial E_{total}}{\partial w_5} = \frac{\partial E_{total}}{\partial \text{out}_{o1}} \times \frac{\partial \text{out}_{o1}}{\partial \text{net}_{o1}} \times \frac{\partial \text{net}_{o1}}{\partial w_5}$$

## Backpropagation - Backward Pass - Output Layer (2/6)

- First, how much does the **total error** change with **respect to the output**? ( $\frac{\partial E_{total}}{\partial out_{o1}}$ )

$$\frac{\partial E_{total}}{\partial w_5} = \frac{\partial E_{total}}{\partial out_{o1}} \times \frac{\partial out_{o1}}{\partial net_{o1}} \times \frac{\partial net_{o1}}{\partial w_5}$$

$$E_{total} = \frac{1}{2}(\text{target}_{o1} - \text{out}_{o1})^2 + \frac{1}{2}(\text{target}_{o2} - \text{out}_{o2})^2$$

$$\frac{\partial E_{total}}{\partial out_{o1}} = -2 \frac{1}{2}(\text{target}_{o1} - \text{out}_{o1}) = -(0.01 - 0.75136) = 0.74136$$

## Backpropagation - Backward Pass - Output Layer (3/6)

- Next, how much does the  $out_{o1}$  change with respect to its total input  $net_{o1}$ ?  
 $\left(\frac{\partial out_{o1}}{\partial net_{o1}}\right)$

$$\frac{\partial E_{\text{total}}}{\partial w_5} = \frac{\partial E_{\text{total}}}{\partial out_{o1}} \times \frac{\partial out_{o1}}{\partial net_{o1}} \times \frac{\partial net_{o1}}{\partial w_5}$$

$$out_{o1} = \frac{1}{1 + e^{-net_{o1}}}$$

$$\frac{\partial out_{o1}}{\partial net_{o1}} = out_{o1}(1 - out_{o1}) = 0.75136(1 - 0.75136) = 0.18681$$

# Backpropagation - Backward Pass - Output Layer (4/6)

- ▶ Finally, how much does the total  $\text{net}_{o1}$  change with respect to  $w_5$ ? ( $\frac{\partial \text{net}_{o1}}{\partial w_5}$ )

$$\frac{\partial E_{\text{total}}}{\partial w_5} = \frac{\partial E_{\text{total}}}{\partial \text{out}_{o1}} \times \frac{\partial \text{out}_{o1}}{\partial \text{net}_{o1}} \times \frac{\partial \text{net}_{o1}}{\partial w_5}$$

$$\text{net}_{o1} = w_5 \times \text{out}_{h1} + w_6 \times \text{out}_{h2} + b_2$$

$$\frac{\partial \text{net}_{o1}}{\partial w_5} = \text{out}_{h1} = 0.59327$$

# Backpropagation - Backward Pass - Output Layer (5/6)

- ▶ Putting it all together:

$$\frac{\partial E_{\text{total}}}{\partial w_5} = \frac{\partial E_{\text{total}}}{\partial \text{out}_{o1}} \times \frac{\partial \text{out}_{o1}}{\partial \text{net}_{o1}} \times \frac{\partial \text{net}_{o1}}{\partial w_5}$$

$$\frac{\partial E_{\text{total}}}{\partial w_5} = 0.74136 \times 0.18681 \times 0.59327 = 0.08216$$

## Backpropagation - Backward Pass - Output Layer (6/6)

- ▶ To **decrease the error**, we subtract this value from the **current weight**.
- ▶ We assume that the **learning rate** is  $\eta = 0.5$ .

$$w_5^{(\text{next})} = w_5 - \eta \times \frac{\partial E_{\text{total}}}{\partial w_5} = 0.4 - 0.5 \times 0.08216 = 0.35891$$

$$w_6^{(\text{next})} = 0.40866$$

$$w_7^{(\text{next})} = 0.5113$$

$$w_8^{(\text{next})} = 0.56137$$

[<https://makeameme.org/meme/oooh-this>]

# Backpropagation - Backward Pass - Hidden Layer (1/8)

- ▶ Continue the **backwards pass** by calculating new values for  $w_1$ ,  $w_2$ ,  $w_3$ , and  $w_4$ .
- ▶ For  $w_1$  we have:

$$\frac{\partial E_{\text{total}}}{\partial w_1} = \frac{\partial E_{\text{total}}}{\partial \text{out}_{h1}} \times \frac{\partial \text{out}_{h1}}{\partial \text{net}_{h1}} \times \frac{\partial \text{net}_{h1}}{\partial w_1}$$

## Backpropagation - Backward Pass - Hidden Layer (2/8)

- ▶ Here, the **output of each hidden layer neuron** contributes to the **output of multiple output neurons**.
- ▶ E.g.,  $out_{h1}$  affects both  $out_{o1}$  and  $out_{o2}$ , so  $\frac{\partial E_{total}}{\partial out_{h1}}$  needs to take into consideration its effect on the both output neurons.

$$\frac{\partial E_{total}}{\partial w_1} = \frac{\partial E_{total}}{\partial out_{h1}} \times \frac{\partial out_{h1}}{\partial net_{h1}} \times \frac{\partial net_{h1}}{\partial w_1}$$

$$\frac{\partial E_{total}}{\partial out_{h1}} = \frac{\partial E_{o1}}{\partial out_{h1}} + \frac{\partial E_{o2}}{\partial out_{h1}}$$

# Backpropagation - Backward Pass - Hidden Layer (3/8)

- ▶ Starting with  $\frac{\partial E_{o1}}{\partial out_{h1}}$

$$\frac{\partial E_{total}}{\partial out_{h1}} = \frac{\partial E_{o1}}{\partial out_{h1}} + \frac{\partial E_{o2}}{\partial out_{h1}}$$

$$\frac{\partial E_{o1}}{\partial out_{h1}} = \frac{\partial E_{o1}}{\partial out_{o1}} \times \frac{\partial out_{o1}}{\partial net_{o1}} \times \frac{\partial net_{o1}}{\partial out_{h1}}$$

$$\frac{\partial E_{o1}}{\partial out_{o1}} = 0.74136, \quad \frac{\partial out_{o1}}{\partial net_{o1}} = 0.18681$$

$$net_{o1} = w_5 \times out_{h1} + w_6 \times out_{h2} + b_2$$

$$\frac{\partial net_{o1}}{\partial out_{h1}} = w_5 = 0.40$$

# Backpropagation - Backward Pass - Hidden Layer (4/8)

- ▶ Plugging them together.

$$\frac{\partial E_{o1}}{\partial out_{h1}} = \frac{\partial E_{o1}}{\partial out_{o1}} \times \frac{\partial out_{o1}}{\partial net_{o1}} \times \frac{\partial net_{o1}}{\partial out_{h1}} = 0.74136 \times 0.18681 \times 0.40 = 0.0554$$

$$\frac{\partial E_{o2}}{\partial out_{h1}} = -0.01905$$

$$\frac{\partial E_{total}}{\partial out_{h1}} = \frac{\partial E_{o1}}{\partial out_{h1}} + \frac{\partial E_{o2}}{\partial out_{h1}} = 0.0554 + -0.01905 = 0.03635$$

# Backpropagation - Backward Pass - Hidden Layer (5/8)

- Now we need to figure out  $\frac{\partial \text{out}_{h1}}{\partial \text{net}_{h1}}$ .

$$\frac{\partial E_{\text{total}}}{\partial w_1} = \frac{\partial E_{\text{total}}}{\partial \text{out}_{h1}} \times \frac{\partial \text{out}_{h1}}{\partial \text{net}_{h1}} \times \frac{\partial \text{net}_{h1}}{\partial w_1}$$

$$\text{out}_{h1} = \frac{1}{1 + e^{-\text{net}_{h1}}}$$

$$\frac{\partial \text{out}_{h1}}{\partial \text{net}_{h1}} = \text{out}_{h1}(1 - \text{out}_{h1}) = 0.59327(1 - 0.59327) = 0.2413$$

# Backpropagation - Backward Pass - Hidden Layer (6/8)

- And then  $\frac{\partial \text{net}_{h1}}{\partial w_1}$ .

$$\frac{\partial E_{\text{total}}}{\partial w_1} = \frac{\partial E_{\text{total}}}{\partial \text{out}_{h1}} \times \frac{\partial \text{out}_{h1}}{\partial \text{net}_{h1}} \times \frac{\partial \text{net}_{h1}}{\partial w_1}$$

$$\text{net}_{h1} = w_1 x_1 + w_2 x_2 + b_1$$

$$\frac{\partial \text{net}_{h1}}{\partial w_1} = x_1 = 0.05$$

# Backpropagation - Backward Pass - Hidden Layer (7/8)

- ▶ Putting it all together.

$$\frac{\partial E_{total}}{\partial w_1} = \frac{\partial E_{total}}{\partial out_{h1}} \times \frac{\partial out_{h1}}{\partial net_{h1}} \times \frac{\partial net_{h1}}{\partial w_1}$$

$$\frac{\partial E_{total}}{\partial w_1} = 0.03635 \times 0.2413 \times 0.05 = 0.00043$$

# Backpropagation - Backward Pass - Hidden Layer (8/8)

- ▶ We can now update  $w_1$ .
- ▶ Repeating this for  $w_2$ ,  $w_3$ , and  $w_4$ .

$$w_1^{(next)} = w_1 - \eta \times \frac{\partial E_{total}}{\partial w_1} = 0.15 - 0.5 \times 0.00043 = 0.14978$$

$$w_2^{(next)} = 0.19956$$

$$w_3^{(next)} = 0.24975$$

$$w_4^{(next)} = 0.2995$$

# Summary

## Summary

- ▶ LTU
- ▶ Perceptron
- ▶ Perceptron weakness
- ▶ MLP and feedforward neural network
- ▶ Gradient-based learning
- ▶ Backpropagation: forward pass and backward pass
- ▶ Output unit: linear, sigmoid, softmax
- ▶ Hidden units: sigmoid, tanh, relu

## Reference

- ▶ Ian Goodfellow et al., Deep Learning (Ch. 6)
- ▶ Aurélien Géron, Hands-On Machine Learning (Ch. 10)
